

# Feathers and Molt

# Feather Structure

# Feather Growth

# Feather Types

- Flight feathers:
  - Remiges (wing primaries and secondaries) — provide thrust and lift<sup>1</sup>.
  - Rectrices (tail feathers) — steering and braking.
- Contour feathers: shape and streamline the body, provide some waterproofing.
- Down and semiplume: insulation and under-layers for contour smoothing.
- Filoplumes: sensory feathers that monitor feather position.
- Bristles: tactile/ protective feathers around bill and eyes.

# Feather Types

A

Tail  
Ruffed Grouse

Wing  
Amazon Parrot

Semiplume  
Northern Cardinal

Contour  
Helmeted Guineafowl

Down  
Canada Goose

Filoplume  
Domestic Chicken

Bristle  
Common Poorwill

B

# Feather Molt

- Molt is a cyclic process driven by hormones
- All birds have a complete molt once a year – the prebasic molt
- Many birds have a second partial molt – the prealternate molt. Contour feathers only.
- The first year of life is different

# Molt and Plumage Terminology

- The *life-year system* describes the appearance of a bird at different seasons or life stages
- Plumage = appearance of the bird

# Molt and Plumage Terminology

- The *Humphrey-Parkes system* describes plumages based on the molt that produced them
- Plumage = a generation of feathers from one molt

Definitive Alternate

# Shorebird Molt

- Molt requires adequate food
- Shorter-distance migrants often molt on breeding grounds, molt quickly
- Long-distance migrants molt on wintering grounds, more protracted
- Some molting may occur in stopover sites

# Feather Coloration

- Birds' eyes are sensitive to a greater portion of the electromagnetic spectrum than humans (both lower and higher wavelengths)
- Bird's eyes have more types of color receptors than humans
- Birds see a wider portion of the spectrum, and can also discern more colors within the spectrum

# Feather Coloration

- Feather colors can be due to pigment, structures, or a combination of both
- Pigment colors – colored substances that absorb white light and emit only certain wavelengths.
- Structural colors – arise from microscopic arrangements of keratin, air, and melanin that scatter light in a way that only certain wavelengths are reflected.

# Feather Coloration

# Feather Coloration

- Melanins – complex molecules found in all vertebrates, most abundant pigments in birds.
- Manufactured within cells, can create intricate patterns.
- Earth tones, black, gray, brown, reddish brown, pale yellow.

# Feather Coloration

- Carotenoids – pigments produced only in plants, acquired in diet
- Produce bright reds, orange, yellow

# Feather Coloration

- Structural Blues – air bubbles within feather's keratin are in a specific ordered distribution, scattering shortest wavelengths back out

# Feather Coloration

- Melanins and carotenoids often layered with structural blues to create vivid hues

# Feather Coloration

- Iridescence – produced when melanin inside barbules is more highly ordered, changing colors with viewing angle.
